BIG DIVE

TECH. CUSTOM EDITION

A project by TOP-IX designed for Intesa Sanpaolo

Recap

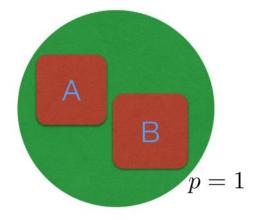

- Data-analytic thinking
- Data quality
- Descriptive statistics
- Correlation & causation
- Bias
- Regression
- Comparison between groups

Probability -basic concepts

$$P(A) = \text{Area of A}$$

$$P(A \text{ or } B) = P(A) + P(B)$$

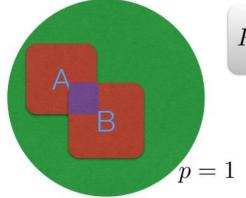

Probability –basic concepts

$$P(A) = \text{Area of A}$$

$$P(B|A) = \frac{P(A \text{ and } B)}{P(A)}$$

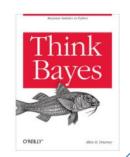

$$P(A|B) = \frac{P(B|A) P(A)}{P(B)}$$

Bayes Theorem

$$P(A \text{ or } B) = P(A) + P(B) - P(A \text{ and } B)$$

 $P(A \text{ and } B) = \text{overlap of A and B}$

Screening test

Your doctor thinks you might have a rare disease that affects **1 person in 10,000**. A test that is **99%** accurate comes out **positive**. What's the probability of you having the disease?

Bayes Theorem:
$$P(disease|positive|test) = \frac{P(positive|test|disease)P(disease)}{P(positive|test)}$$

Finally:
$$P(disease|positive \ test) = 0.0098$$

Screening test

Consider a population of 1,000,000 individuals. The numbers we should expect in the **contingency**

matrix are:	Marginals

		disease	no disease	V
	positive	99	9,999	10,098
	negative	1	989,901	989,902
Ma	rginals———	100	999,900	1,000,000

$$\begin{split} P\left(disease|positive\ test\right) &= \frac{TP}{TP + FP} = 0.0098 \\ P\left(no\ disease|negative\ test\right) &= \frac{TN}{TN + FN} = 0.99999 \end{split}$$

Screening test

Consider a population of 1,000,000 individuals. The numbers we should expect in the **contingency**

Marginals

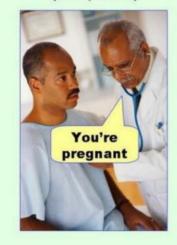

matrix are:

		disease	no disease	•
	positive	99	9,999	10,098
	negative		989,901	989,902
Mai	rginals———	100	999,900	1,000,000

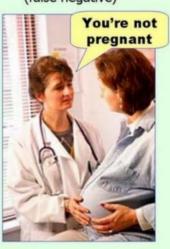

$$P\left(disease|positive\ test\right) = \frac{TP}{TP + FP} = 0.0098$$

$$P\left(no\ disease|negative\ test\right) = \frac{TN}{TN + FN} = 0.99999$$

Type I error (false positive)

Type II error (false negative)

Consider a second screening

Bayes Theorem still looks the same: $P\left(disease|positive\ test\right) = \frac{P\left(positive\ test|disease\right)P\left(disease\right)}{P\left(positive\ test\right)}$

but now the probability that we have the disease has been updated: $P^{\dagger} \left(disease
ight) = 0.0098$

So this time we find: P^{\dagger} (disease|positive test) = 0.4949

Each test is providing **new evidence**, and Bayes theorem is simply telling us how to use it to **update our beliefs**.

Confusion Matrix

Testure	positive	negative
positive	TP	FP
negative	FN	TN

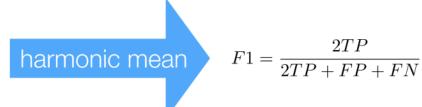

$$accuracy = \frac{TP + TN}{TP + TN + FP + FN}$$

$$specificity = \frac{TN}{FP + TN} \bigcirc$$

$$\bigcirc sensitivity = \frac{TP}{TP + FN}$$

$$F1 = \frac{2TP}{2TP + FP + FN}$$

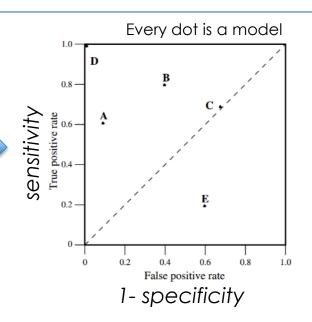

Confusion Matrix - ROC curve

Feature Test	positive	negative
positive	TP	FP
negative	FN	TN

$$sensitivity = \frac{TP}{TP + FN}$$

$$specificity = \frac{TN}{FP + TN}$$

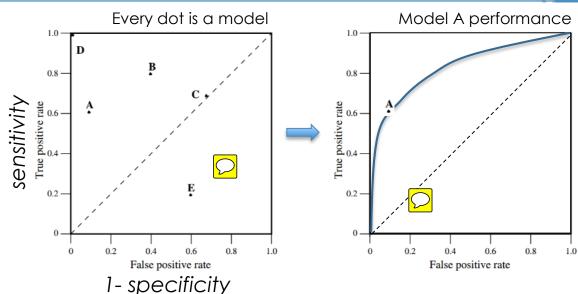

Confusion Matrix - ROC curve

Feature Test	positive	negative
positive	TP	FP
negative	FN	TN

$$sensitivity = \frac{TP}{TP + FN}$$

$$specificity = \frac{TN}{FP + TN}$$

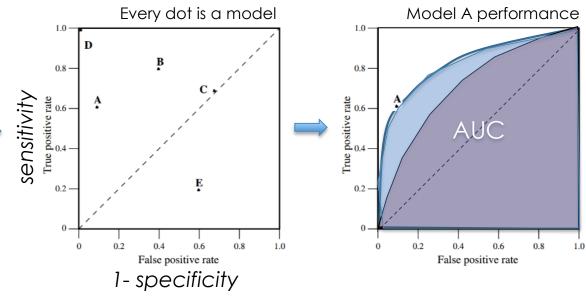

Confusion Matrix - ROC curve

Feature Test	positive	negative
positive	TP	FP
negative	FN	TN

$$sensitivity = \frac{TP}{TP + FN}$$

$$specificity = \frac{TN}{FP + TN}$$

An introduction to ROC analysis
